ABSTRACT: Two groups of mutually perpendicular molybdenum buses, one of them covered with a Pb-Sb alloy, the other with an In-Ga alloy, were fused into a p-type Ge plate with p-n junctions produced beforehand by diffusion. The buses were prepared by the method of photolithography. The alloys were deposited on the buses by the thermal method. After the fusing of the buses, the Ge plate was etched in H_2O_2 until the Ge was completely removed outside the bus intersections. [Translation of abstract]

TITLE: On Kuban' Soil

PERIODICAL: Nauka i zhizn', 1959, Nr 7, p 64 (USSR)

ABSTRACT: The article is concerned with oil and gas production in the Kuban' area (Krasnodarskiy kray). A new oil-producing area near the Stanitsa (Cossack village) Troitskaya has developed into the biggest oil field of the above area, with light products' content 2 to 3 times higher than in other oil-producing areas of the USSR. By 1965, oil production there will grow by 150%. In 1957, all of the USSR yielded 20 billion cu m of natural gas. The Kuban' area alone is scheduled to produce this amount within 7 to 8 years. The following cities will be supplied with gas from the Kuban' area: Moscow, Leningrad, Rostov, Kerch', Simferopol', and Sevastopol'. The Kuban'-Moscow Gas Pipeline, the construction of which is already under

Card 1/2

On Kuban' Soil

way, will supply gas to Moscow by 1965. The Kuban' Circular Gas Pipeline, also called Krasnodar Circular Gas Pipeline, is also under construction. It will link Armavir, Kropotkin, and other localities. The new gas pipeline is being laid at the rate of 1,000 m or more per working day. There is 1 sketch, 1 vignette, and 1 full-page color drawing.

TITLE: Design and some ion-optical characteristics of an electrostatic focusing system

SOURCE: Moscow. Inzhenerno-fizicheskii institut. Fizicheskaya elektronika, no. 2, 1965, 15-26

TOPIC TAGS: electrostatics, ion beam focusing, mass spectrometry

ABSTRACT: The authors present equations for multielectrode electrostatic focusing systems for use in crossed-field mass-spectrometer^{44,55} analyzers. Unlike two-electrode capacitors, the electrostatic focusing system described can be used to obtain fields of cylindrical, spherical, and toroidal configuration. In addition, by suitable choice of electrode potentials it is possible to produce an axially-symmetrical electric field, which cannot be produced by ordinary capacitors. The ion-optical characteristics of the electrostatic focusing system can be varied over a wide range by varying the electrode potentials. The equations for first-order focusing by means of this system are calculated by standard procedures. The electrode arrangement is shown in Fig. 1 of the Enclosure. A focusing system with electrodes spaced 1.3 mm apart (d_k) and with height (h_k) 5 mm and average radius

Card 1/3

L 3405-66

0

of curvature 140 mm, and subtending an angle (ψ) of 60° (total of 76 electrodes) was tested for focusing ability by means of a special set-up. Two types of field were used in the electrostatic focusing system, quasi-homogeneous and toroidal. The quasi-homogeneous field was used to determine the focusing of the beam and the dispersion, and the toroidal field to determine the dispersion and the effective angle of deflection. The experimental results agreed with the theoretical ones in spite of the fact that the precision and dimensional tolerances of the system were not too high. Orig. art. has: 8 figures, 13 formulas, and 1 table.

TITLE: Observations of the Effect of Temporary Hypothermy in the Life Activity of Old Rats (Nablyudeniye nad deystviyem vremennoy gipotermii na zhiznedeyatel'nost' starykh krys).

PERIODICAL: Doklady AN SSSR, 1957, Vol. 117, Nr 3, pp. 539-541 (USSR)

ABSTRACT: To lower the body temperature with warm-blooded animals down to 18-20° leads, at a prolonged duration, to a disturbance of the metabolism. The resulting lack of oxygen in tissues, in the first place in the brains, leads to an activation of neurotic processes and finally to the death of the organism. The artificial hibernation at a diminishing of the body temperature only by 10-15° below the normal value, can be endured by a healthy warm-blooded animal without any pathological after-effects. The artificial hibernation (at 29-32°) has found wide-spread application in surgery during the passed years. The effect of a temporary hypothermy with animals, however, have not been studied so far. While a short-termed hypothermy with young rats (even down to 14-15°) did not have any negative consequences, with old rats it resulted already at a lowering down to 20° in death, sometimes. To be sure, the mortality of many old

Card 1/3

Observations of the Effect of Temporary Hypothermy in the Life Activity of Old Rats 20-3-51/52

rats can be brought to their senility and decay of health. At the latter experiments the authors have applied the method of an automatic thermoregulation by means of a contact thermometer and lowered the body temperatures down to 23-27°. This enabled them to prolong the duration of the hypothermy up to 10 hours. After the application of the hypothermy the animals were kept under normal vivarium-conditions. Earlier experiments, in 1950, have shown, that a temporary hypothermy exercises a beneficent effect upon old rats and their life activity: The animal grew more mobile, the appetite improved, the coat was renewed. According to this it was assumed that also the procreativeness could be activated by the hypothermy. At experiments which followed with physiologically sterile males at an application of the hypothermy four to five times, it was proved that they regained their procreativeness and procreated 1-4 litters. All this shows that the influence of such an unfavourable factor, which the hypothermy appears to be, leads to a peculiar "rejuvenation" of the organism. Apparently a reaction system is formed which represents a biological autokatalysis. This effects that under the influence of un-

Card 2/3

Observations of the Effect of Temporary Hypothermy in the Life Activity of Old Rats 20-3-51/52

favourable factors active substances are which entail an essential animation of the metabolism reactions. There are 1 table, and 11 references, 7 of which are Slavic.

The practical value of the sulfite method for preparing Al_2O_3 from Ukrainian kaolins is described. The kaolin is fired at 800° to 900° and treated with SO_2 at 50° to 60° and 7 atm. At 80° to 100°, most of the Al sulfite (containing 29% Al_2O_3) precipitates out from the solution. The precipitate is ignited, and the SO_2 is recovered. The Al_2O_3 is then purified by the Bayer method. In another case the kaolin is fired and then treated with 25% HNO_3 in an autoclave at 150°, and the $Al(NO_3)_3$ is crystallized. The latter is decomposed by heating to 400° to 500°, or the $Al(NO_3)_3$ solution is neutralized with NH_3. In the first modification the HNO_3 is recovered, while in the second NH_4NO_3 is obtained. The use of HNO_3, however, involves corrosion problems.</p>																										COMMON VARIABLES INDEX										COMMON ELEMENTS

(U.S.S.R.)</i>, 13, 719-22 (1940).—For the purpose of obtaining a highly refractory silicon carbide compound material, a batch consisting of kaolin and clay with an excess of coal was prepared without an addition of metallic iron. In this way the formation of ferrosilicon was obviated, and all of the reduced silica combined with surplus carbon, giving SiC according to the reaction $Al_2O_3 \cdot 2SiO_2 + 6C = Al_2O_3 + 2SiC + 4CO$. The reaction between kaolin and coal begins at 1450°C, and ends at about 1700°C. A refractory was obtained by mixing the product with 10% plastic refractory clay and calcining it. Its melting point was 1890°C. Its deformation under load approximates its melting temperature.</p>

Effect of the initial cathode surface on the structure of electrolytic copper. N. A. Alarchenko and A. N. Sysoyev. *Zhur. Priklad. Khim.* 25, 1216-18 (1952). Cu was deposited from a soln. of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ 200 and H_2SO_4 60 g./l. on cathodes of rolled Cu (I), amalgamated Cu (II), graphite (III), and Al (IV), with a c.d. of 1, 2.5, 5, and 8 amp./sq. dm. until a deposit of 0.8 mm. Cu was obtained. Plots of η vs. t , min., showed that for I η was const.; for the other cathodes, deposition of Cu did not take place at equil. η (0.304 v.). For II and III deposition began at more pos. values of η and these approached a const. value after 20 min. which was explained by depolarization of the Hg for II and absorption effects due to porosity of III. With IV, deposition began at more neg. values and these approached constancy after 25-30 min. This was explained by the difficulty of forming an initial crystal lattice of Cu on Al and Al_2O_3 . The initial deposit had no effect on the crystal orientation but affected the texture and the crystal size. The latter increased with the c.d. and was greater on III.

TITLE: Comparative Investigation of a Chrome-plating Process in Baths of Standard Type and Combination Types (Sravnitel'noye issledovaniye protsessa khromirovaniya v vannakh standartnogo i kombinirovannogo tipov)

PERIODICAL: V sb.: Teoriya i praktika elektrolit. khromirovaniya. Moscow, AN SSSR, 1957, pp 61-76

ABSTRACT The effect of additions of various anions and cations and their combinations on the process of chrome plating was investigated. A customary standard bath containing 250 g of CrO_3 and 2.5 g of H_2SO_4 per liter of solution was taken to serve as a term of comparison. A study of polarization characteristics of Cr deposition, hardness measurements, and metallographic and X-ray examinations revealed the following: Addition of various cations in the form of sulfate compounds in quantities equivalent to 1% of H_2SO_4 in terms of the weight of CrO_3 has comparatively little effect on the results of chrome plating;

Card 1/2

Comparative Investigation of a (cont.)

simultaneous introduction of additions of various anions increases the current efficiency and widens the ranges of working temperatures and of cd during which bright deposits are obtained; a smaller decrease in current efficiency with an increase of temperature is characteristic of combination baths as compared to the standard bath; Cr deposits produced in combination baths possess sharply defined structural characteristics which differentiate them from deposits produced in standard baths; introduction of SiF_6^{2-} and F^- anions as catalysts of the chrome-plating process does not result in high values of the current efficiency, but causes uneven quality of the coatings produced. In order to increase the current efficiency, produce non-porous coatings, and make possible automation of the chrome-plating process, the use of simultaneous additions of various anions is recommended. In the article, "Method of Covering the Surfaces of Heated Metals with Titanium," A. N. Sysoyev and A. K. Beskrovnyy describe a method of covering surfaces of heated metals with titanium by using a process of thermal decomposition of titanium iodides in a vacuum. It differs from other methods in that in the increasing of the corrosion resistance of metals the processing is carried out by the application of high frequency current heating.

A patent was granted this method under Class 48, Chemical Treatment of Metals - Class 48c, 1104, No 104988, 30 April 1951 at the Ministry of Machine and Instrument Building USSR. (Byulleten' Izobreteniy, No 1, Jan 57, p 48) (U)

TITLE: Study of Cathodic Films Formed in Electrolysis of Chromic Acid

PERIODICAL: Zhurnal prikladnoy khimii, 1960, Vol 33, Nr 2, pp 372-378 (USSR)

ABSTRACT: Chemical composition, properties, and mechanism of formation of cathodic films formed upon electrolysis of pure chromic acid were studied. Copper and steel cathodes of 0.1 dm^2 surface area and platinum and lead anodes were used. The electrolyte was aqueous solution of CrO_3 without SO_4 ions. Dense cathodic films were obtained at current density $D_c = 20-25 \text{ amp/dm}^2$ (C stands for cathode), temperature of electrolyte $35-50^\circ$, concentration of CrO_3 200-250 g/l

NOV/20-34-2-10/52

Chemical analysis of the cathodic films showed that they consist mainly of trivalent chromium, probably in the form of $\text{Cr}(\text{OH})_3$. Upon dissolution of the film in hot (80-90°) $6\text{N H}_2\text{SO}_4$ or 0.1N HCl, a thin continuous deposit of metallic chromium is disclosed underneath the film, indicating that discharge of chromium ions takes place underneath the dense, non-porous film. These facts indicate that the hexivalent chromium ions are reduced to metallic chromium step-wise rather than directly. Study of the film properties has shown high corrosion stability, poor solubility in acids and bases, high oil absorption power (40%), strong adherence to the metal surface and to paint coatings. These properties suggest that the cathodic films can be used as ground coats under paints. There are 4 figures; 2 tables; and 15 references, 6 Soviet, 4 German, 5 U.S. The U.S. references are: Sargent, Trans. Am. Electroch. Soc.,

TITLE: A self-regulating tetrachromate electrolyte

PERIODICAL: Zhurnal prikladnoy khimii, v. 33, no. 10, 1960,
2261 - 2267

TEXT: The principle of self-regulating electrolytes is the control and maintenance of $(\text{CrO}_3/\text{SO}_4) \approx 100$ in the cell, which in normal runs has to be controlled by sampling and chemical assay. This complicates the plating process and does not maintain the stability. The self-regulating electrolyte is based on the use of catalysts in form of acids or salts which are sparingly soluble in the chromium electrolyte. For this aim the strontium sulphate and hydrogen silicophosphate salts of alkali metals are used. The self-regulating electrolyte is based on the resulting solutions and corresponding anion equilibria present in the solution and excess salt where solubility in the electrolyte is governed by the optimum concentra-

A self-regulating tetrachromate ...

tion of catalyst anions in the cell. The authors then point out that the solubility of CaSO_4 could be lowered by means of CaCO_3 so that the following relation is held: $(\text{Ca}^{++}) \cdot (\text{SO}_4^{--}) = 17 P_{\text{CaSO}_4} =$

$= \text{const.}$ This was used as the basis in investigating the self-regulating electrolyte of so-called tetrachromate type. In order to investigate the possible use of CaSO_4 as an added catalyst in self-regulating electrolytes the solubility of CaSO_4 in chromic acid solutions was determined, as well as the effect of temperature and CrO_3 concentration on CaSO_4 solubility. The determination was done over periods ranging from a few days to 6 months. The results show that use of a saturated CaSO_4 solution for the region of large concentrations yields the SO_4^{--} which at a concentration of the order of

700 g/l reaches the optimum $\frac{\text{SO}_4^{--}}{\text{CrO}_3} \cong 0.01$. It should be noted that

Card 2/5

25061

S/080/60/033/010/013/029

D216/D306

A self-regulating tetrachromate ...

with the increase in temperature the solubility of CaSO_4 for the medium concentrations (200-400 g/l CrO_3) increases while at 1000 g/l of CrO_3 the solubility does not change with temperature. The solutions with concentration of CrO_3 of 250 g/l heated to 100°C dissolve more than 50 gms. of CaSO_4 which on cooling down deposits the large crystals of $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$. The appearance of supersaturation and metastable compositions in H_2CrO_4 is small. The nature of CaSO_4 solubility in CrO_3 is not clear. As shown by K.G. Parfenov, the solubility of CaSO_4 in H_2SO_4 solutions containing 50, 100, 200 gms. of H_2SO_4 per liter is not high. It is suggested that chromic acid reacts with CaSO_4 in following way $\text{H}_2\text{Cr}_2\text{O}_7 + \text{CaSO}_4 \rightleftharpoons \text{H}_2\text{SO}_4 + \text{CaCr}_2\text{O}_7$ which could proceed without a change in the pH of the solution. The reversible character of CaSO_4 solubility in chromic

Card 3/5

A self-regulating tetrachromate ...

acid is of a great interest in the field of chromium plating. The solubility of CaSO_4 may be lowered by increasing the concentration of Ca^{++} by means of CaCO_3 . It was established that at CrO_3 concentration of 250-300 g/l, an addition of 50-70 g/l of CaCO_3 resulted

in optimum ratio $\frac{\text{CrO}_3}{\text{SO}_4^{--}} \approx 100$, hence the principle of self-regula-

tion. The current efficiency was determined simultaneously on three solutions. The results show that maximum efficiency is obtained at a CrO_3 concentration of 300 g/l - this solution in the main corresponds to the calcium tetrachromate. To determine and compare the current efficiencies of different electrolytes three were chosen; (1) normal tetrachromate (2) standard and (3) self-regulating tetrachromate. The results obtained at 20°C show that the self-regulating electrolyte indicates the highest current efficiency. The plating was polishable, (obtained at 10-50 A/cm² and 18-25°C) 114.

Card 4/5

had a thickness of 200 μ (at 40 A/dm² at 20°C), hardness $H_v = 804$ and a low porosity of 20 - 25 μ . This high density of the plating suggests that by using a self-regulating electrolyte, the direct plating of steel can be achieved without the use of a Cu or Ni base. TITLE: Comparative investigations of certain electrochemical properties of germanium and tin

PERIODICAL: Zhurnal prikladnoy khimii, v. 34, no. 9, 1961,
2001 - 2007

TEXT: The probability of the future application of non-aqueous electrolytes for the deposition of germanium and germanium alloys has prompted the authors to investigate certain electrochemical properties of germanium and tin. Tin was chosen as the object of comparison because its chlorides form complexes with ethylene glycol similar to those formed with germanium chloride; also, germanium and tin form alloys, the addition of small quantities of another metal to which may prevent the polymorphic transformation of tin (at approximately -130°) which would permit a more reliable protection of tin-coated metals. Deposition of germanium was studied

Card 1/4

Comparative investigations of ...

27344
S/080/61/034/009/007/016
D204/D305

by plotting polarization curves. A plate or a round rod of copper was used as the cathode and a graphite rod of cylindrical shape and large surface area, as the anode. A saturated calomel half-cell was used as the reference electrode. The ethylene glycol used was distilled at 195-197°. GeCl_4 for one series of experiments was synthesized from germanium dioxide and concentrated HCl , while the commercially pure grade containing hydrochloric acid was used for another. The electrolytes used contained 1, 1.4 and 4 volume % GeCl_4 in glycol. The cathode processes were studied over wide ranges of current densities at 18 and 60° with and without agitation of the electrolyte. The duration of polarization for all experiments was 12 minutes. It was found that metallic germanium was deposited from a solution containing 4 volume % of anhydrous GeCl_4 at 60° at current densities of 0.2 A/dm^2 and above, 0.3-0.4 A/dm^2 being the upper current density limit. At concentrations of 1 and 1.4 volume % at normal as well as elevated temperatures, a dark, smeary film forms at the cathode (probably $\text{GeO} \cdot n\text{H}_2\text{O}$) with simulta-

Card 2/

neous evolution of hydrogen. The formation of a complex of the $(\text{CH}_2\text{OHCH}_2\text{O})_2\text{GeCl}_2$ -type does not cause the germanium deposition potential to be shifted in the negative direction. The polarization curves for tin have the typical form of the curves obtained during electrolytic deposition of germanium. Metallic deposits of a silvery white color are obtained from an electrolyte of $\text{SnCl}_4 \cdot 5\text{H}_2\text{O}$ in ethylene glycol containing 18 g/l Sn, at current densities of 0.2-1.5 A/dm². On further raising the current density, spongy deposits form. From solutions containing Sn^{2+} , spongy deposits are obtained at current densities of 0.2-0.3 A/dm², and with further increase in current density, these are transformed to dendrites. SYSOYEV, A. Ye.

Sysoev, A. E. Some cases of integrability of differential equations of the 1st order. Uspehi Matem. Nauk (N.S.) 7, no. 2(48), 175-179 (1952) (Russian)

Let $F(x, y) = \varphi(x, y)$, $G(x, y) = \psi(x, y)$ be functions of x, y which are pairwise independent and let $F(\varphi, \psi)$ be the function obtained from $F(x, y)$ by making the substitution $\varphi = \varphi(x, y)$, $\psi = \psi(x, y)$. The author calls $F(x, y)$ homogeneous of degree n with respect to $\varphi(x, y)$, $\psi(x, y)$ if $F(t\varphi, t\psi) = t^n F(\varphi, \psi)$, and remarks that necessary and sufficient for this to hold is $\partial(F/\varphi^n, \psi/\varphi)/\partial(x, y) = 0$. He applies this result to find equations of the form

$$y' = Q(x)y + M(x)y^2 + N(x)y^3 + \dots + P(x)y^n$$

which have a general solution of the form $G(\varphi) = cF(\psi/\varphi)$.

Casting of Steel Trolley Wheels in Metal Moulds. D. I. Sysoyev and A. A. Barannikov. (*Hutník*, (Prague), 1951, 1, No. 9, 105-108). [In Czech]. A detailed description is given of the development of a continuous, mechanized, mass-production method of making cast steel trolley wheels, carried out in the Voroshilov Machine Building Plant in the U.S.S.R. In the new process complete wheels are cast in batteries of metal moulds, the design of which, and difficulties which had to be surmounted in the process of developing them, are described. — P. P.
